AI Model Output Risk Identification & Structured Evaluation Framework

Name: Dharshika S
Program: B.Tech – Artificial Intelligence and Data Science

Introduction

Artificial Intelligence systems generate large volumes of automated responses across domains such as healthcare, finance, education, and social discussions. While these systems enhance efficiency and accessibility, they may also produce outputs containing bias, misinformation, harmful advice, or ethically non-compliant content.

The purpose of this project is to systematically evaluate AI-generated outputs, identify potential risks, classify their severity, and recommend corrective actions. This study demonstrates structured analytical reasoning and risk identification capabilities aligned with responsible AI practices.

Objective

The objectives of this evaluation are:

- To identify potential ethical and compliance risks in AI-generated content.
- To categorize risks into structured classifications.
- To assign severity levels (Low, Medium, High).
- To provide clear justifications and mitigation recommendations.
- To demonstrate readiness for AI risk and compliance evaluation roles.

Risk Categories Used

The following categories were used to classify risks:

• Bias Risk

Generalized stereotypes or discriminatory statements related to gender, religion, culture, age, socioeconomic status, or mental health.

• Harmful Advice Risk

Medical, financial, or behavioral advice that may cause real-world harm.

• Misinformation Risk

Factually incorrect or misleading statements.

• Unsupported / Hallucinated Claims

Fabricated statistics, exaggerated guarantees, or speculative predictions without evidence.

• Compliance & Ethical Risk

Encouragement of illegal activity, violence, or violation of fairness principles.

Methodology

A structured evaluation framework was applied:

1. Twenty AI-generated outputs were collected across diverse domains.
2. Each output was independently analyzed.
3. Risk Type was identified based on predefined categories.
4. Risk Level was assigned:
    - High Risk: Severe harm, discrimination, or legal violation potential.
    - Medium Risk: Moderate misleading or biased content.
    - Low Risk: Minor exaggeration or limited impact.
5. Each case included a written explanation, impact assessment, and recommended corrective action.

This methodology ensured objectivity and consistency in evaluation.

Summary of Findings

The 20 evaluated outputs included themes such as:

- Gender-based generalizations
- Religious comparisons
- Financial guarantees
- Medical advice
- Illegal activity encouragement
- Mental health oversimplification
- Security and privacy advice
- Absolute claims about AI systems

Risk Distribution:

- High Risk: [Insert Count]
- Medium Risk: [Insert Count]

- Low Risk: [Insert Count]

High-risk cases were primarily associated with discriminatory stereotypes, harmful medical or financial advice, and encouragement of illegal actions. Medium-risk cases largely involved unsupported claims or overgeneralizations.

Key Observations

The evaluation revealed several important patterns:

- Statements targeting protected groups often resulted in high bias risk.
- Absolute language such as “always” or “guaranteed” frequently increased misinformation risk.
- Medical and financial advice requires strong verification and disclaimers.
- AI outputs may appear confident even when unsupported.
- Human oversight remains critical for high-risk domains.

Recommendations

Based on the findings, the following actions are recommended:

1. Implement automated bias detection mechanisms.
2. Introduce verification systems for statistical and factual claims.
3. Include mandatory disclaimers for medical and financial content.
4. Establish human review processes for high-risk outputs.
5. Regularly audit AI systems for fairness and compliance alignment.

Conclusion

This project demonstrates a structured and systematic approach to evaluating AI-generated content for ethical, safety, and compliance risks. Through classification and impact analysis of 20 outputs, key risk patterns were identified and mitigation strategies were proposed.

The study highlights the importance of structured evaluation frameworks in ensuring AI systems remain responsible, fair, and aligned with ethical standards. Developing such risk identification methodologies is essential for supporting trustworthy AI deployment.
